
GoOutside: From Scattered CSVs to a Data-Driven Solution

From a lake to a warehouse

GoOutside's Data Analyst left, and over three years of sales data were stuck in four CSV files: retailers, products, order methods and daily sales (about 149,000 rows).

Two questions needed answers:

- **Dustin** (Retail Partnerships): how is each market composed, and what target fits it?
- **Sarah** (Finance): which order methods justify their personnel costs?

One warehouse, different ways to use it

BigQuery

The data warehouse. One view joins the four files and calculates revenue, cost and profit

Google Sheets

For raw data exploration and automatic updates

Data Studio dashboard, with filters by date

Limits and next steps

What to keep in mind

- Personnel costs per order method are not in the data, so we show each method's contribution, not whether it pays off.
- Orders are estimated (22.7K estimated orders = 149.3K order lines): there is no order ID, so we built one from retailer, date and order method.
- Data runs from Jan 2015 to Jul 2018, so 2018 is incomplete.
- Markets are classified with a 75% cutoff (revenue held by the top 3 retailers) that we chose, and "sales volume" is measured as revenue in euros.

Next steps

- Add personnel cost per order method.
- Load new sales data into BigQuery, and the Sheet and the dashboard follow.

Thanks for your attention

The warehouse is ready, and each new question is
one query away
